Introduction to Relational Databases and SQL

What is a Relational Database?

- Relational databases store related data in tabular form
- Relationships between tables are defined with keys (primary and foreign)
- Most relational databases are created for use by applications and optimized for CRUD transactions
 - Create
 - Read
 - Update
 - Delete
- Data Analysts/Data Scientists mostly focused on Read querying the data.
 They want to look at the data and perform calculations without making any permanent changes.

What is SQL

SQL stands **S**tructured **Q**uery **L**anguage. It is the language you use to interact with a database. It allows you to write out what you want to search for, goes to a database that you specify, then returns those results to you. As a Data Analyst you will be able to look at, and perform calculations on the data, but not make any permanent changes.

The Structured part of SQL means queries are written in a specific format using specific keywords.

Keywords

- SELECT
- FROM
- AS
- LIMIT
- DISTINCT
- COUNT
- WHERE
- AND
- OR
- BETWEEN

- IN
- (NOT) NULL
- LIKE
- AVG(), SUM(), MAX(), MIN(), etc.
- ORDER BY
- GROUP BY
- HAVING

Queries are written following this basic format:

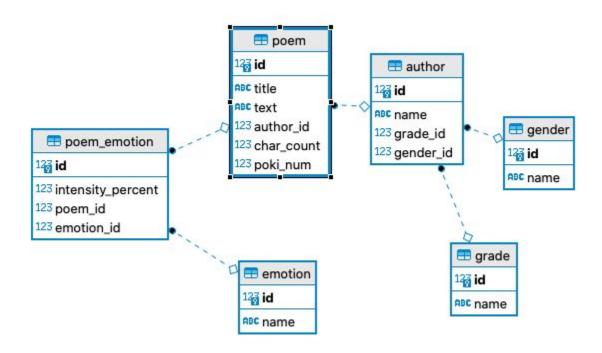

SELECT columns
FROM table
WHERE condition
GROUP BY columns
HAVING condition
ORDER BY columns

It's helpful to know that the query **executes** in a different **order**:

FROM
WHERE
GROUP BY
HAVING
SELECT

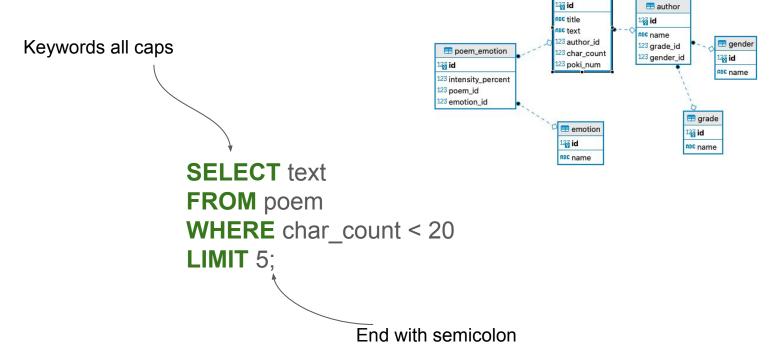

For our learning examples, we will be using the PoetryKids database. Below is an Entity Relationship Diagram (ERD) that shows the tables in the database and the relationships between tables.

Format of a Query

m poem

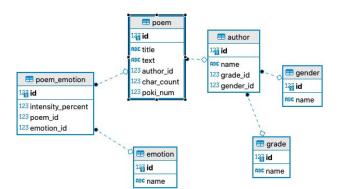

Selecting all columns from a table

When writing a query you indicate what columns you want to see. These directions go in the **SELECT** statement. A shorthand to **SELECT ALL** is to use a *:

SELECT * **FROM** emotion;

	[PK] integer	character varying
1	1	Anger
2	2	Fear
3	3	Sadness
4	4	Joy

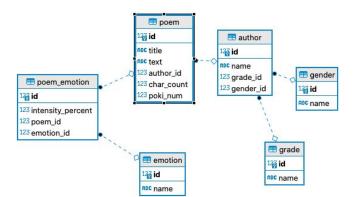

Selecting single columns from a table

You can also specify individual columns to return, each separated by a ',':

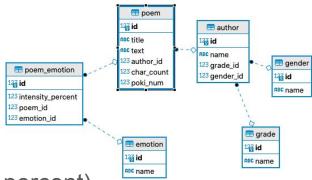

SELECT name, grade_id **FROM** author **LIMIT** 5;

4	name character varying	grade_id integer	
1	а		1
2	aab		1
3	aadhya		1
4	aaliyah		1
5	aanna		1

Aggregating Data

You may want to summarize your data in different ways. For example you could **COUNT**, **SUM**, **AVERAGE**, or find the **MAX** or **MIN**:

SELECT COUNT(id) **FROM** author **WHERE** grade_id = 4;

SELECT AVG(intensity_percent) **FROM** poem_emotion **WHERE** emotion_id = 2;

Joining Data

Often data will be spread across **multiple tables**. In order to perform an analysis you may need to **combine the data from two or more tables**. Joins in SQL are just like merging with pandas.

Table A		
id	col_1	col_2
1	23-B	12
2	435	45
3	AB145	23
4	ВВ	56
5	435	123

merge_table			
id	col_1	col_2	col_a
1	23-B	12	а
2	435	45	а
3	AB145	23	b
4	BB	56	b
5	435	123	а

Table B		
id	lookup_id	col_a
a1	1	а
a2	2	а
b1	3	b
b2	4	b
a3	5	а

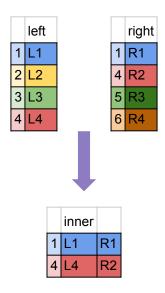

INNER JOIN

Combining data from a **left** and **right** table is called **JOIN**ing. There are multiple kinds of joins and each one combines the data in a different way.

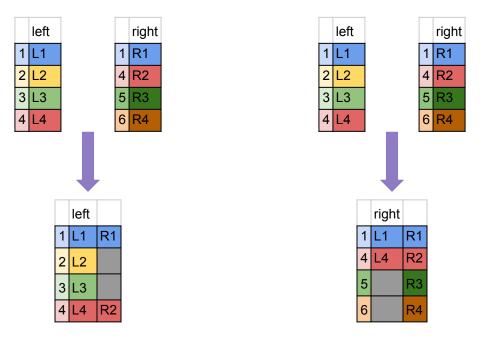

An **INNER JOIN** keeps **only the rows that have matching values in both tables**. This is the default type of join if you just use the **JOIN** keyword in your query.

LEFT JOIN and RIGHT JOIN

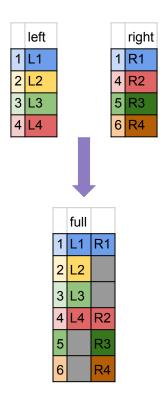

A **LEFT JOIN** keeps **all** rows from the left table and all **matching** rows from the right table. A **RIGHT JOIN** works similarly, except all rows from the right table are kept.

FULL JOIN (Sometimes called An OUTER JOIN depending on the SQL dialect)

A FULL JOIN keeps all rows from both tables:

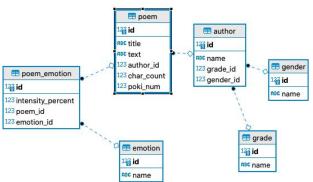

Aggregating Data with GROUP BY

The **GROUP BY** keyword will subdivide the table based on the specified columns. You can then perform aggregations on the subgroups:

SELECT AVG(char_count) **FROM** poem **JOIN** author on poem.author_id = author.id **GROUP BY** grade_id;

4	avg numeric
1	189.8826185101580135
2	179.7968655816757083
3	228.0627091773824203
4	201.2769757542106237
5	165.7313291139240506

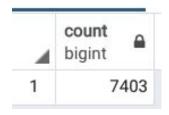

Finding unique values

Sometimes a particular column or a calculation will result in duplicate values. To get just unique values:

SELECT COUNT (DISTINCT name) **FROM** author;

Selecting/avoiding null values

Null values will likely exist in any data set you work with. It will be useful to identify or exclude records with null values:

SELECT title, char_count FROM poem WHERE title IS NOT NULL LIMIT 5;

4	title character varying	char_count integer
1	Computer	106
2	Angel	164
3	Nature Nature and Nat	491
4	Jack	74
5	When I awoke one mor	325
